The BSP model considers communication actions en masse. This has the

effect that an upper bound on the time taken to communicate a set of data can be given. BSP considers all communication actions of a superstep as one unit, and assumes all individual messages sent as part of this unit have a fixed size.

BSP Model. The bulk synchronous parallel (BSP) model was developed by Leslie Valiant in the 1980s. The BSP model is intended as a bridging model between parallel hardware and software. It is an elegant and simple model that has a small and easy to understand interface. The BSP model is defined on an abstract computer called a BSP computer.

The BSP Programming Model In BSP, a parallel program runs across a set of virtual processors (called processes to distinguish them from physical processors), and executes as a sequence of parallel supersteps separated by barrier synchronizations. Each superstep is composed of three ordered phases ...

In this work we use the BSP/CGM parallel computation model [3, 15]. It consists of a set of p processors, each having a local memory of size $O(n/p)$, where n is the problem size. The BSP/CGM parallel computing model is a realistic model where special attention is given to minimize communications overheads.
